ACTUAL APP SCREENSHOT GUIDE

FD Macro Generator Tool Guide

This guide is built for support agents: each screenshot is a control map, and each note explains when to use the control, what data to enter, and what output the agent should copy or verify.

The Macro Generator tab is intentionally excluded. Covered tabs: Price Lookup, Funding Macro, Position History Open & Close Price Calc., and Margin Restrictions.

> All time fields in these tools should be entered in UTC using `YYYY-MM-DD HH:MM:SS`.

Checks price behavior around a timestamp, range, target price, trailing stop, one-second trades, or Mark vs Last gap.

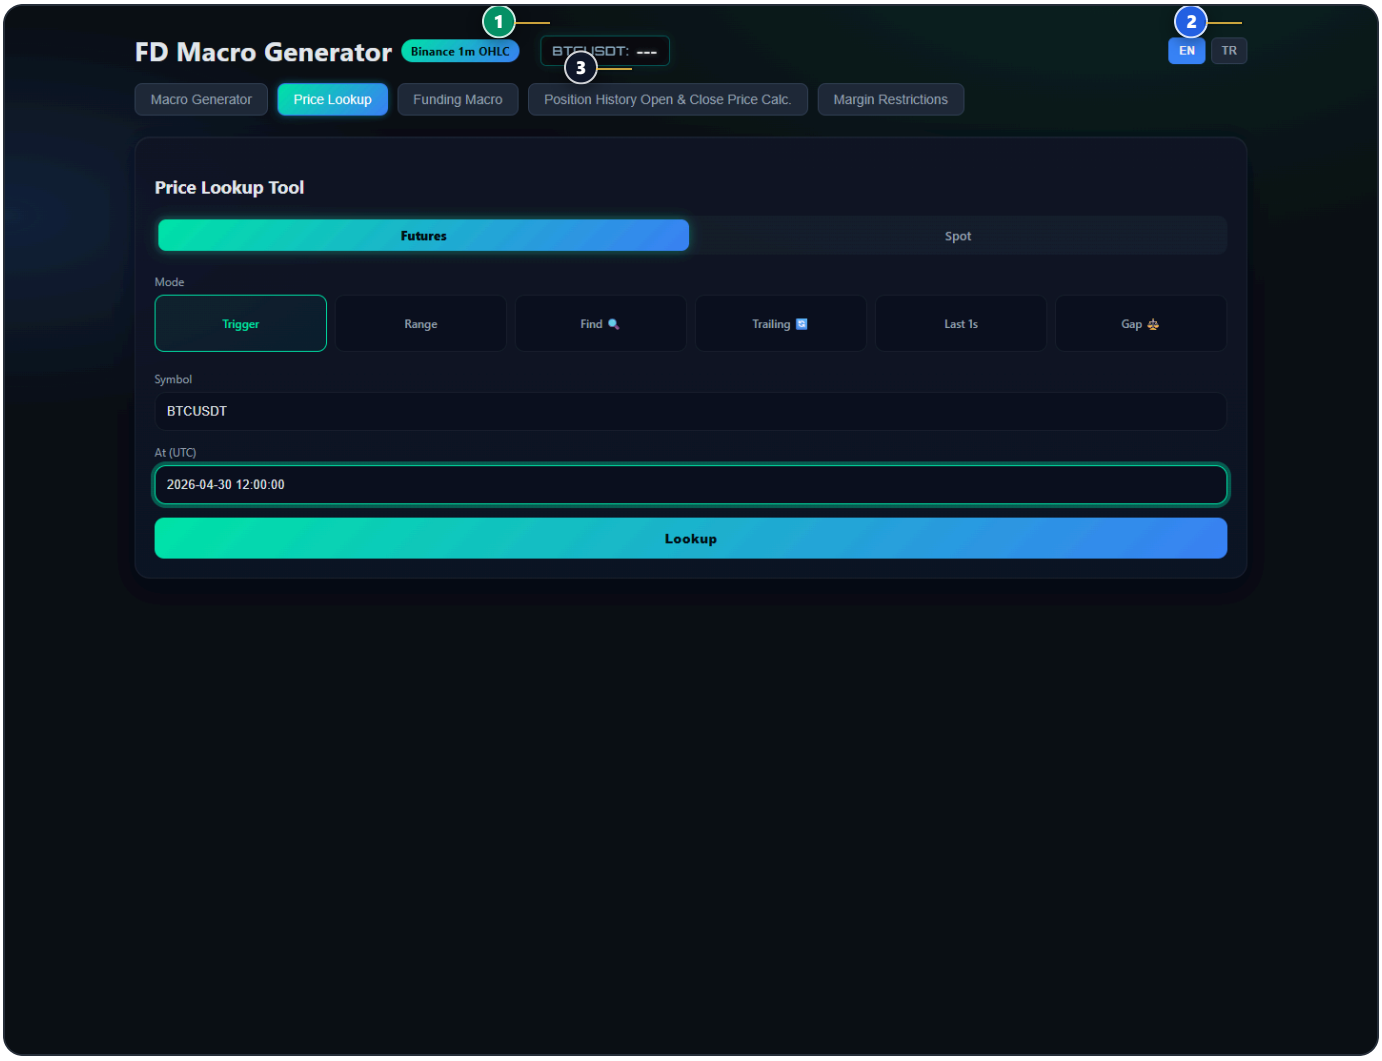
Creates a customer-ready funding fee explanation using nearest funding data, side, size, mode, and tone.

Parses Binance position history and builds average entry and close explanations.

Checks Binance Margin restricted assets and prepares customer-ready answers with the correct FAQ links.

Shared Header

These controls appear above every tab. The screenshot below uses the Price Lookup tab as the example.



1. Shows the active symbol and recent 1 minute Binance OHLC status. It is informational and helps agents keep the current symbol in view.

2. Switches the application language. This guide uses English UI labels.

3. Switches between Macro Generator, Price Lookup, Funding Macro, Position History Open & Close Price Calc., and Margin Restrictions.

Price Lookup - What It Does

Price Lookup is the investigation tab. It pulls public Binance market data and turns it into support-friendly evidence. Use it when a customer asks whether a trigger was reached, why a trailing stop did or did not trigger, or why Mark Price and Last Price behaved differently.

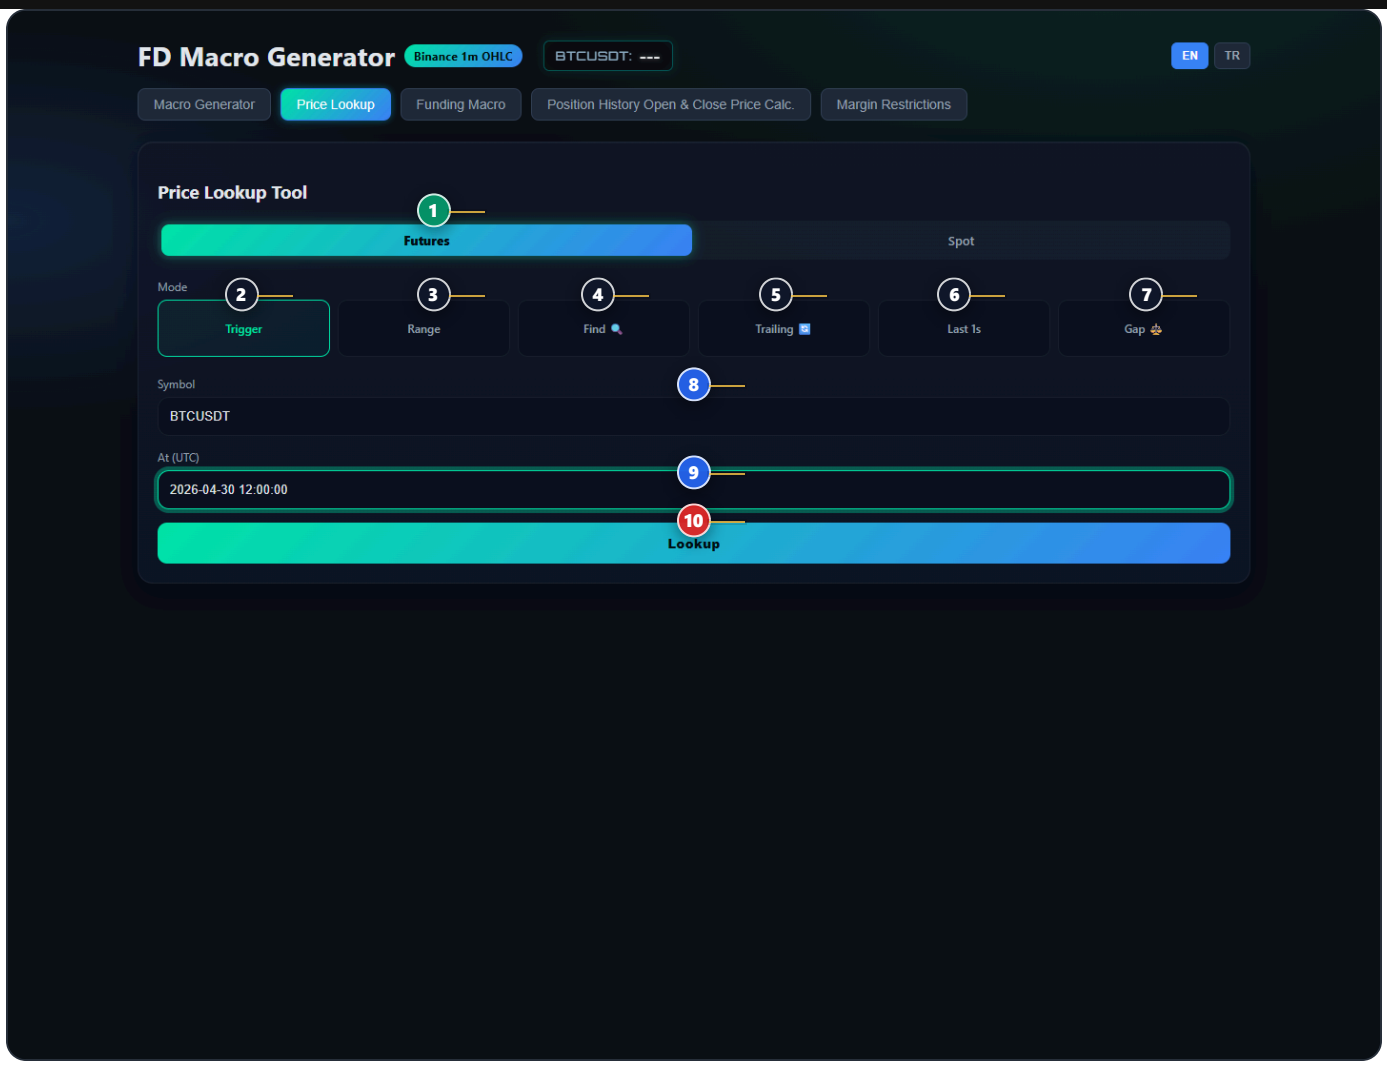
Agent workflow for Price Lookup

- Match the customer's order market first. Futures cases usually need Futures, not Spot.
- Match the order's trigger source. If the order used Mark Price, use Mark Price in Find, Trailing, or Gap checks.
- Use the customer's exact UTC timestamps whenever possible. For live/open cases, use Present Time only for the end of the range.
- After clicking Lookup, copy the generated result only after checking that symbol, market, price source, and period match the case.

1. **Select market.** Use Futures when the order belongs to Futures. Use Spot only for spot-market checks. Futures can compare both Mark Price and Last Price.
2. **Select a mode.** Trigger, Range, Find, Trailing, Last 1s, and Gap each answer a different investigation question.
3. **Enter symbol and UTC time fields.** The symbol is shared with the live ticker, and all timestamps must be UTC.
4. **Pick mode-specific options.** Examples: Target Price, Last/Mark radio buttons, Long/Short direction, Activation Price, Callback Rate, or trigger type.
5. **Click Lookup.** The result appears in a textarea that can be copied into the agent workflow.

Trigger Mode

Use this mode when: the case asks what the 1 minute candle showed at the trigger timestamp. It is best for stop/take-profit cases where the customer gives a single execution or trigger time.



1. Choose the market source. Futures returns Mark Price and Last Price data; Spot returns Last Price data.

2. Checks the 1 minute OHLC candle at the exact trigger timestamp.

3. Finds highest, lowest, timestamp of each, and volatility across a time window.

4. Searches whether a target price was touched in the selected period. If not reached, it reports the closest miss.

5. Replays a trailing stop using direction, activation price, and callback rate.

6

Builds one-second OHLC from recent individual trades. Binance trade data is limited to the recent window.

7

Compares Mark Price and Last Price over the same period to explain trigger disputes.

8

Trading pair to investigate, for example `BTCUSDT` .

9

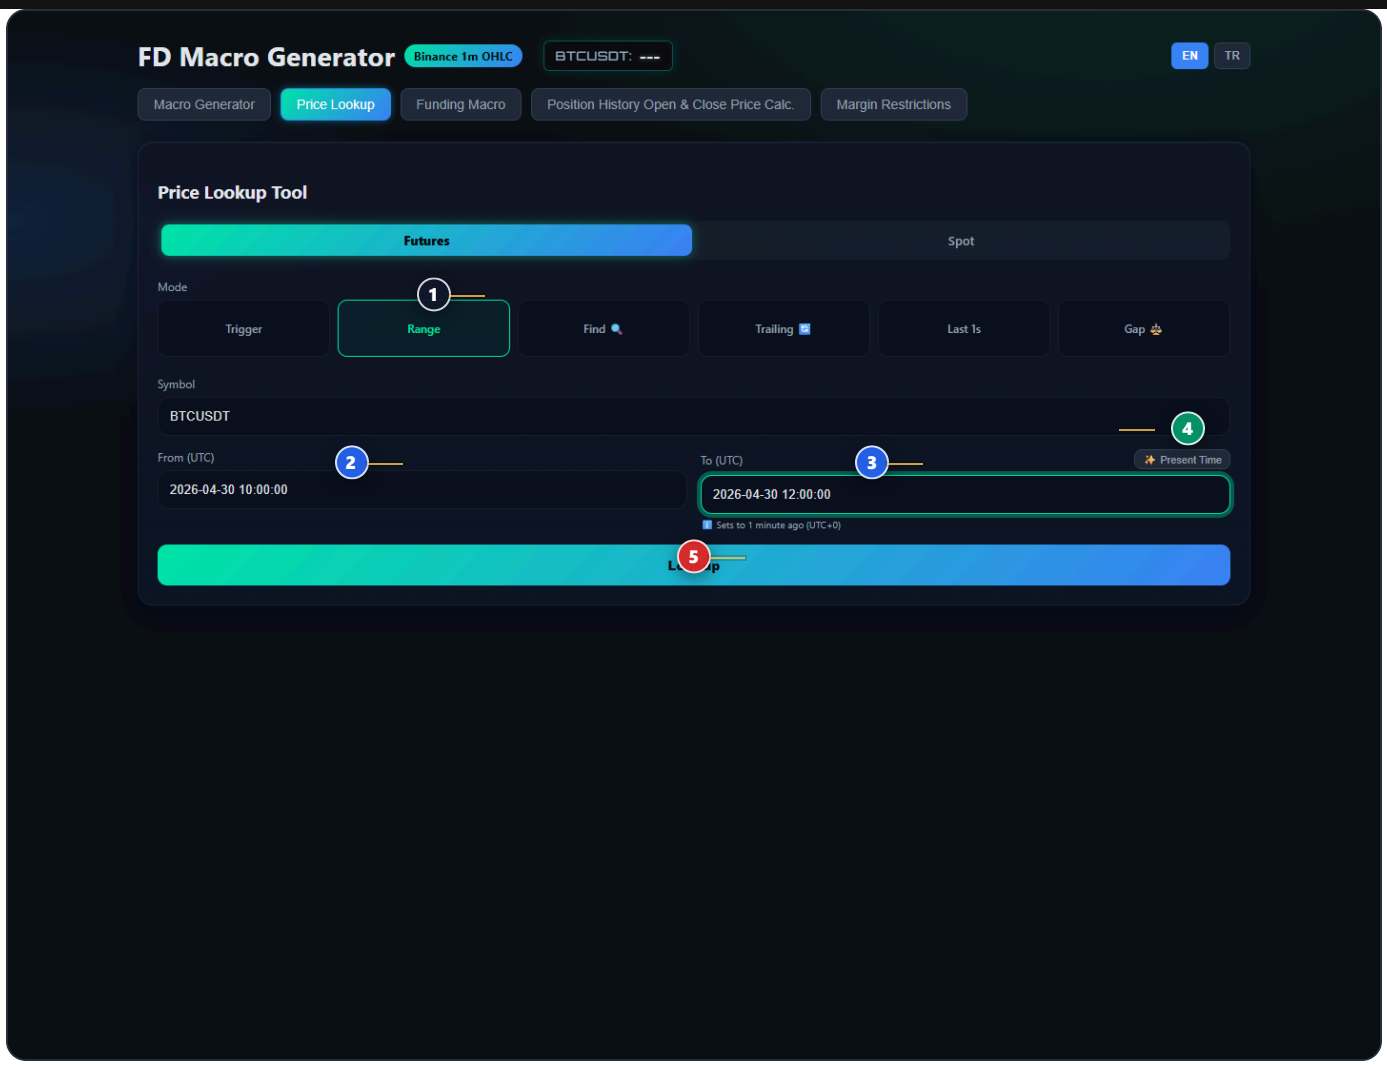
The timestamp to inspect in Trigger or Last 1s mode.

10

Runs the selected investigation and writes the evidence into the result box.

Range Mode

Use this mode when: the agent needs the highest and lowest price during a period, usually to summarize market movement between order placement and cancellation/expiry.



1. Use when the customer asks about the highest/lowest price during a period.

2. Start of the investigation window.

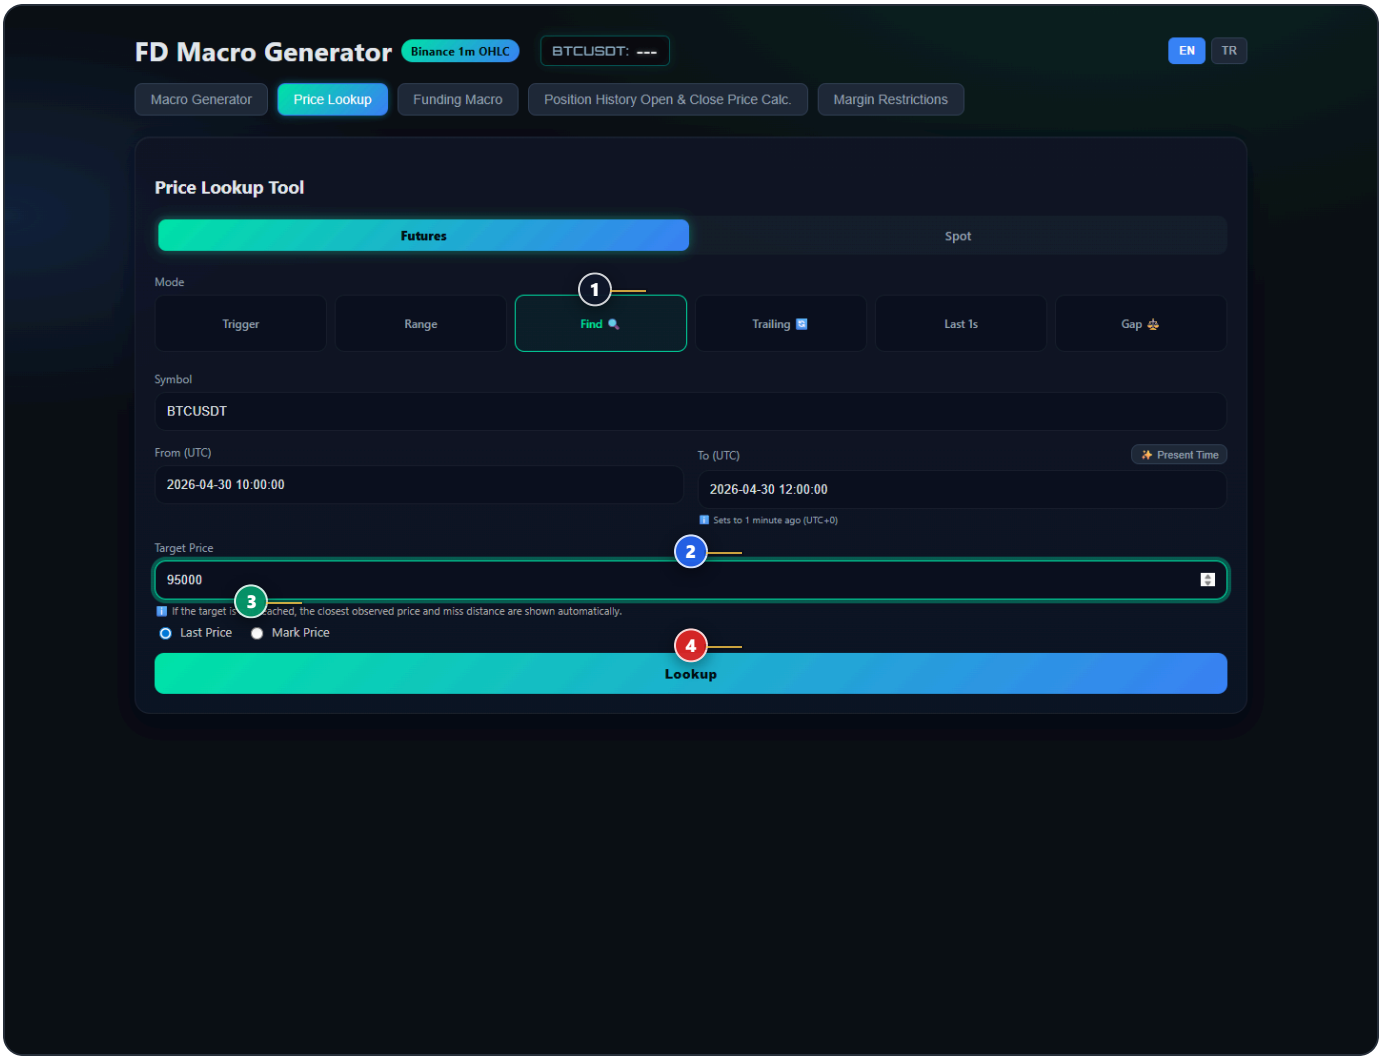
3. End of the investigation window.

4. Sets the To field to about one minute ago in UTC. Use it for live or still-open cases.

5. Returns period high, low, time of high/low, and volatility.

Find Mode

Use this mode when: the customer asks whether a specific price level was reached. The output tells the agent either the first touch time or the closest miss.



1. Use to prove whether a target price was reached and identify the first contact time.

2. The price level the customer claims was touched or not touched.

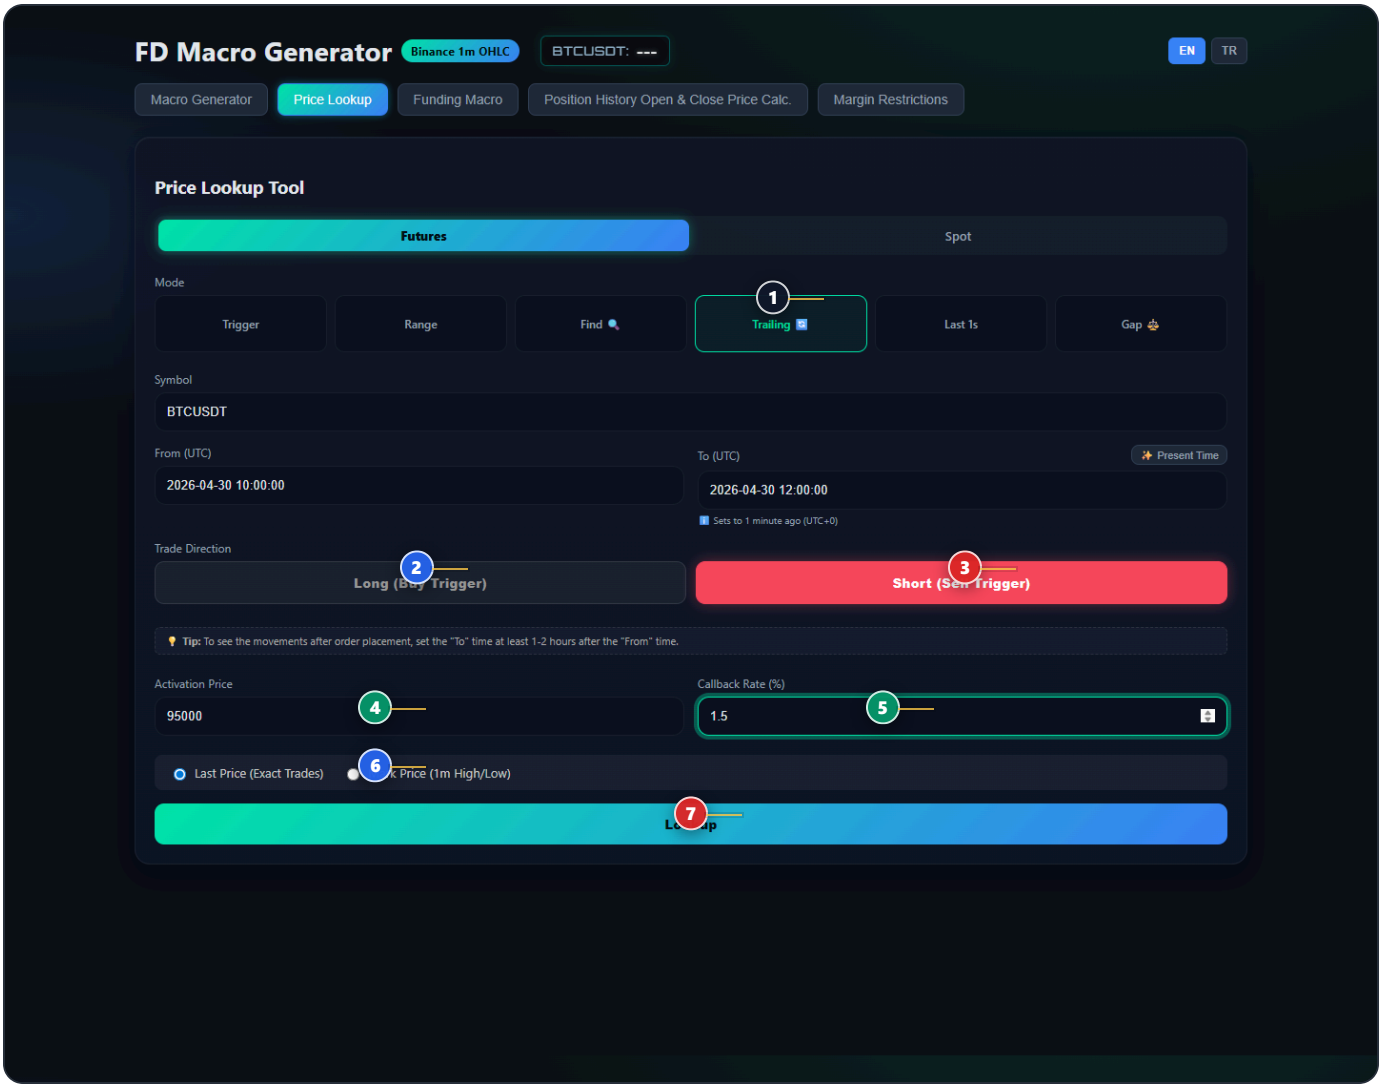
3. For Futures, choose the trigger source used by the order. Spot uses Last Price only.

4

If reached, returns first contact time. If not reached, returns closest observed price and miss distance.

Trailing Mode

Use this mode when: a trailing stop complaint needs a step-by-step explanation of activation, peak/trough tracking, callback percentage, and final trigger status.



1

Use for trailing-stop complaints. The tool checks activation, reference peak/trough, callback movement, and trigger state.

2

Use when a trailing buy should trigger after price rebounds from the trough.

3. Use when a trailing sell should trigger after price pulls back from the peak.

4. The order first becomes active only after this price condition is met.

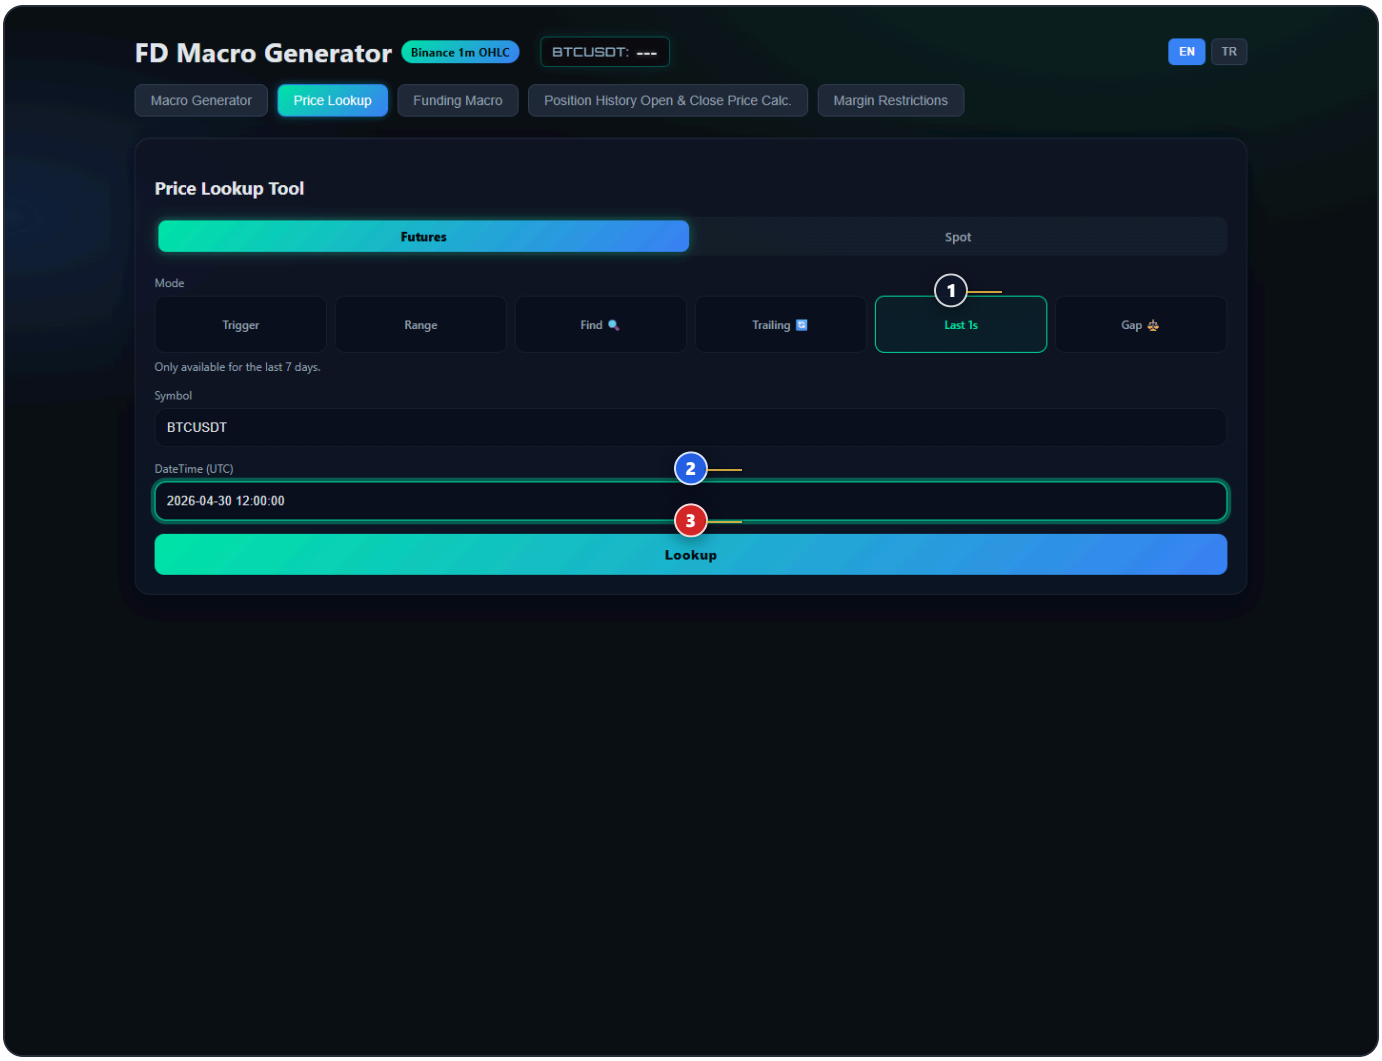
5. The required percentage pullback or rebound after activation.

6. Choose Last Price for exact trade evidence or Mark Price for mark-triggered Futures orders.

7. Produces an agent summary explaining activation, reference point, next trigger level, or trigger time.

Last 1s and Gap Modes

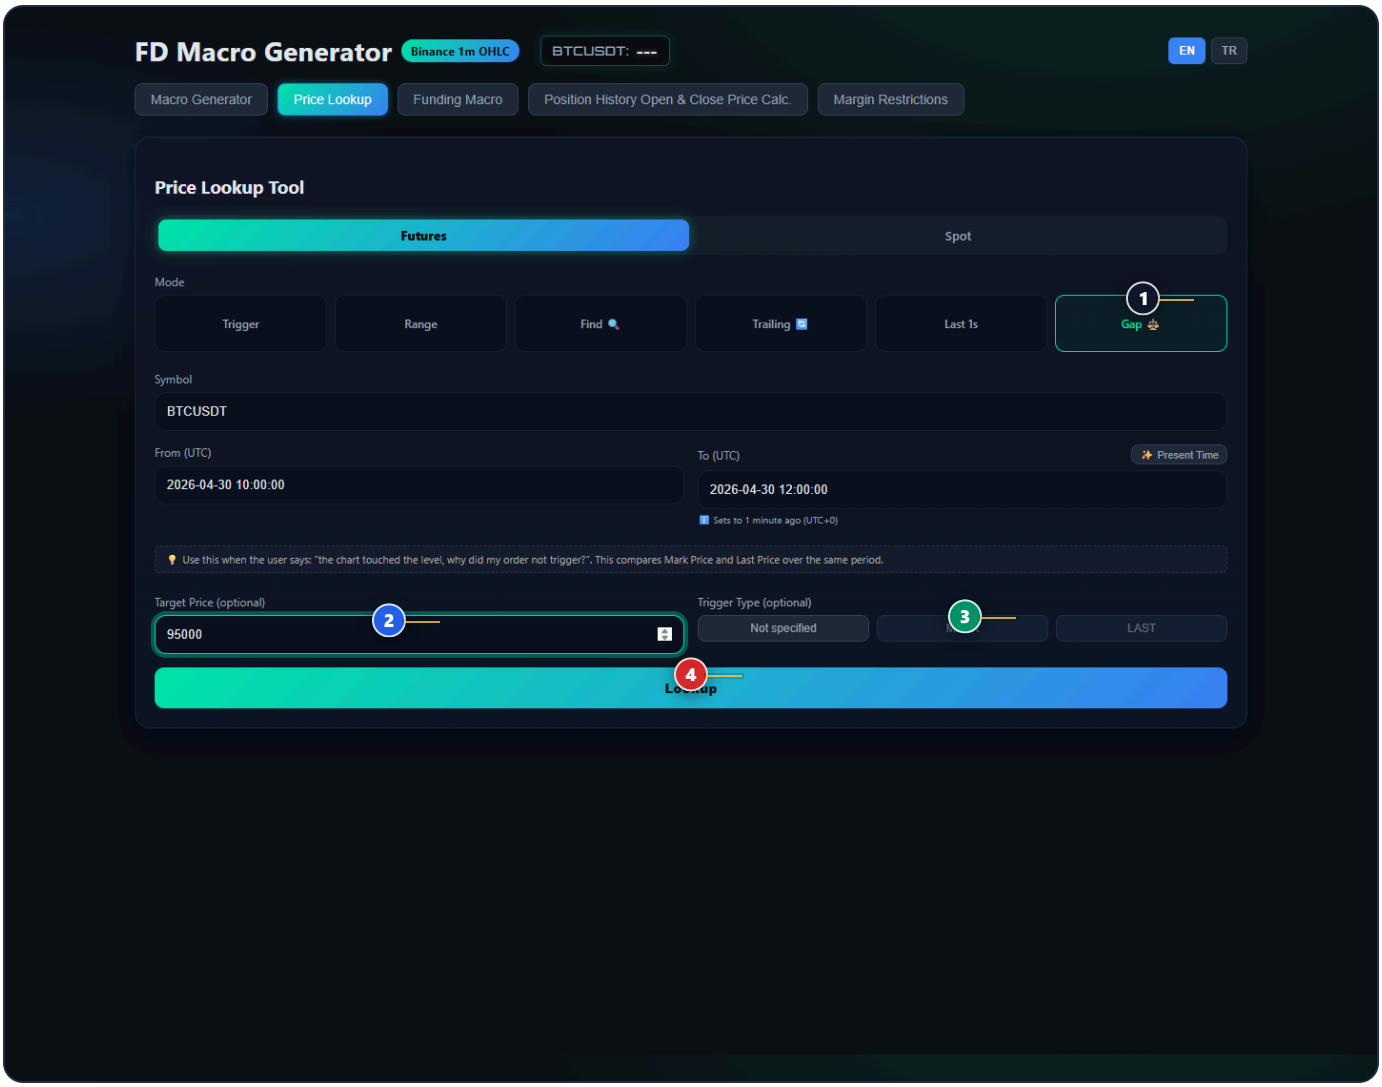
Use these modes when: Last 1s is for exact one-second trade evidence; Gap is for explaining why a chart based on Last Price can differ from a Mark Price-triggered order.



1. Checks exact trade activity inside one second.

2. The second to inspect.

3. Returns one-second open, high, low, close, and trade count.



1. Use when the chart touched a level but the order did not trigger.

2. Optional. Add it when the customer mentions a specific level.

3. Choose Not specified, MARK, or LAST to match the customer order settings.

4. Compares Mark Price vs Last Price and writes a support explanation.

Example Price Lookup answer

The target price was not reached by Mark Price during the selected period. The closest observed Mark Price was 94,980 at 2026-04-30 11:24:00 UTC, which remained 20 USDT away from the target.

Example trailing answer

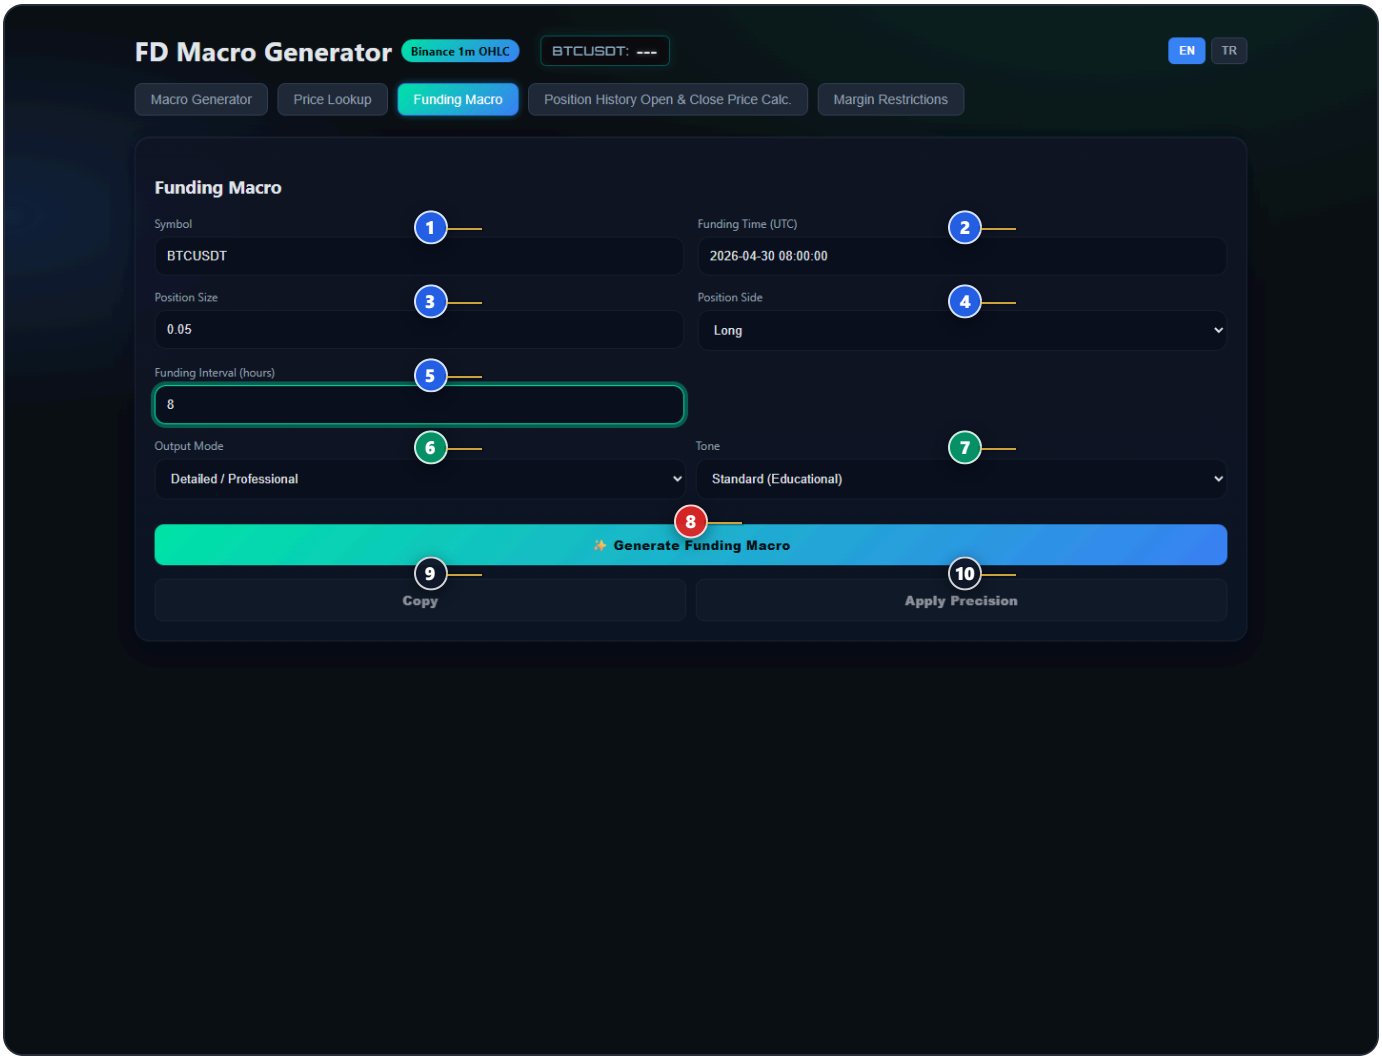
The order activated at 10:18:00 UTC. After activation, the highest Last Price was 95,200. With a 1.5% callback, price needed to pull back to 93,772. It only pulled back 0.8%, so the trailing stop did not trigger.

Funding Macro

Funding Macro builds a customer-ready explanation from funding time, position size, side, interval, output mode, and tone.

Agent workflow for Funding Macro

- Enter the exact symbol, funding time, position size, side, and funding interval from the customer's case.
- Use Detailed / Professional when the customer needs evidence; use Summary for shorter replies.
- Generate first, then use Apply Precision if the reply needs Binance symbol precision applied to the mark price.
- Copy is intentionally disabled until a macro exists, so agents cannot copy an empty answer.



1. Futures symbol, for example `BTCUSDT` .
2. The funding timestamp to investigate. The tool finds the nearest funding record.
3. The customer's position size used in the funding fee calculation.
4. Long or Short. This affects whether the customer paid or received funding.
5. Funding cycle in hours, commonly 8, but some symbols can use other intervals.
6. Detailed / Professional gives full evidence; Summary is shorter.
7. Controls the wording style: Standard, Professional, Empathetic, or Direct.
8. Fetches funding data and writes the answer into the result box.
9. Copies the generated macro. It stays disabled until a result exists.
10. After generation, truncates mark price using Binance exchange precision and regenerates the answer.

Example Funding Macro answer

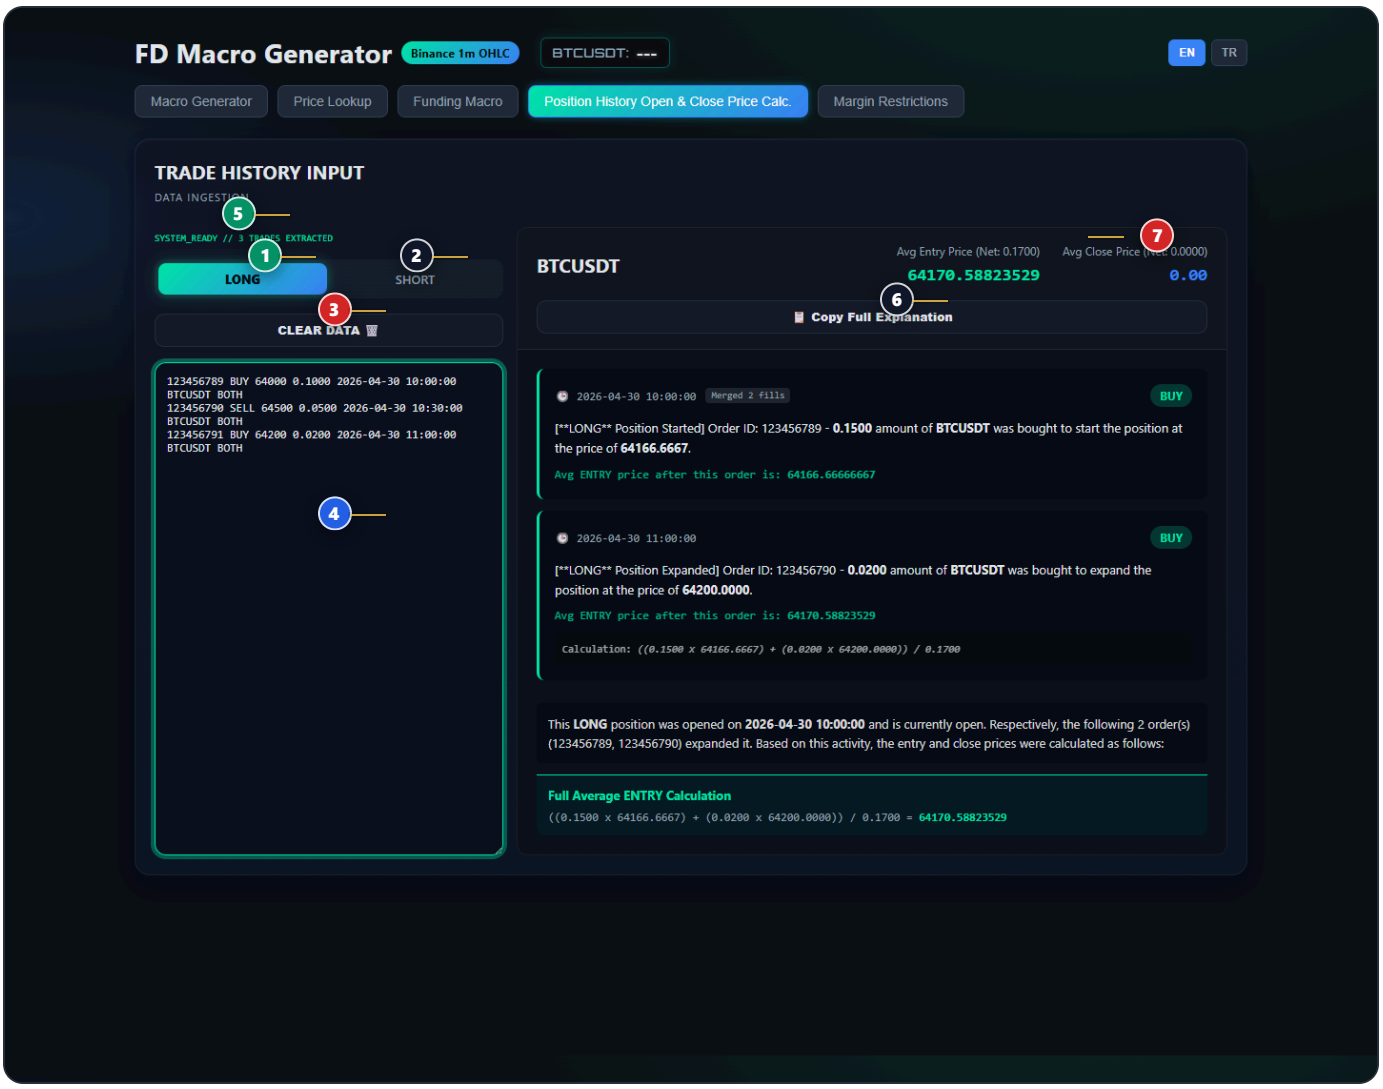
At the selected funding time, the funding rate was applied to the notional value of the position. Based on the customer's Long side and position size, this explains why the funding fee was charged or credited.

Position History Open & Close Price Calc.

This tab parses Binance order history rows and generates average entry and close explanations for support replies.

Agent workflow for Position History Calculator

- Paste the raw Binance order history rows directly into the input area. Parsing runs automatically.
- Use LONG or SHORT only to guide one-way interpretation. Hedge-mode rows with LONG/SHORT/BOTH are detected from the pasted data.
- Check the extracted trade count before copying. If the status says 0 trades, the pasted rows are not in a parseable format.
- Use Copy Full Explanation when the parsed summary matches the customer's symbol and position flow.



1. Interprets one-way BUY activity as opening or expanding a long unless hedge side data says otherwise.

2. Interprets one-way SELL activity as opening or expanding a short unless hedge side data says otherwise.

3. Resets pasted input, parsed trades, calculated results, and status.

4. Paste Binance order history rows here. Parsing runs automatically; there is no Generate button.

5. Shows whether parsing is ready and how many trades were extracted.

6. Copies the complete customer-ready explanation, including formulas and phase summaries.

7. Shows calculated average entry and average close values for the parsed symbol.

Example average calculator answer

```
The LONG position started with order 123456789 and was expanded by order 123456790. The average
entry was calculated as ((0.1500 x 64166.6667) + (0.0200 x 64200.0000)) / 0.1700 = 64170.58823529.
```

Margin Restrictions

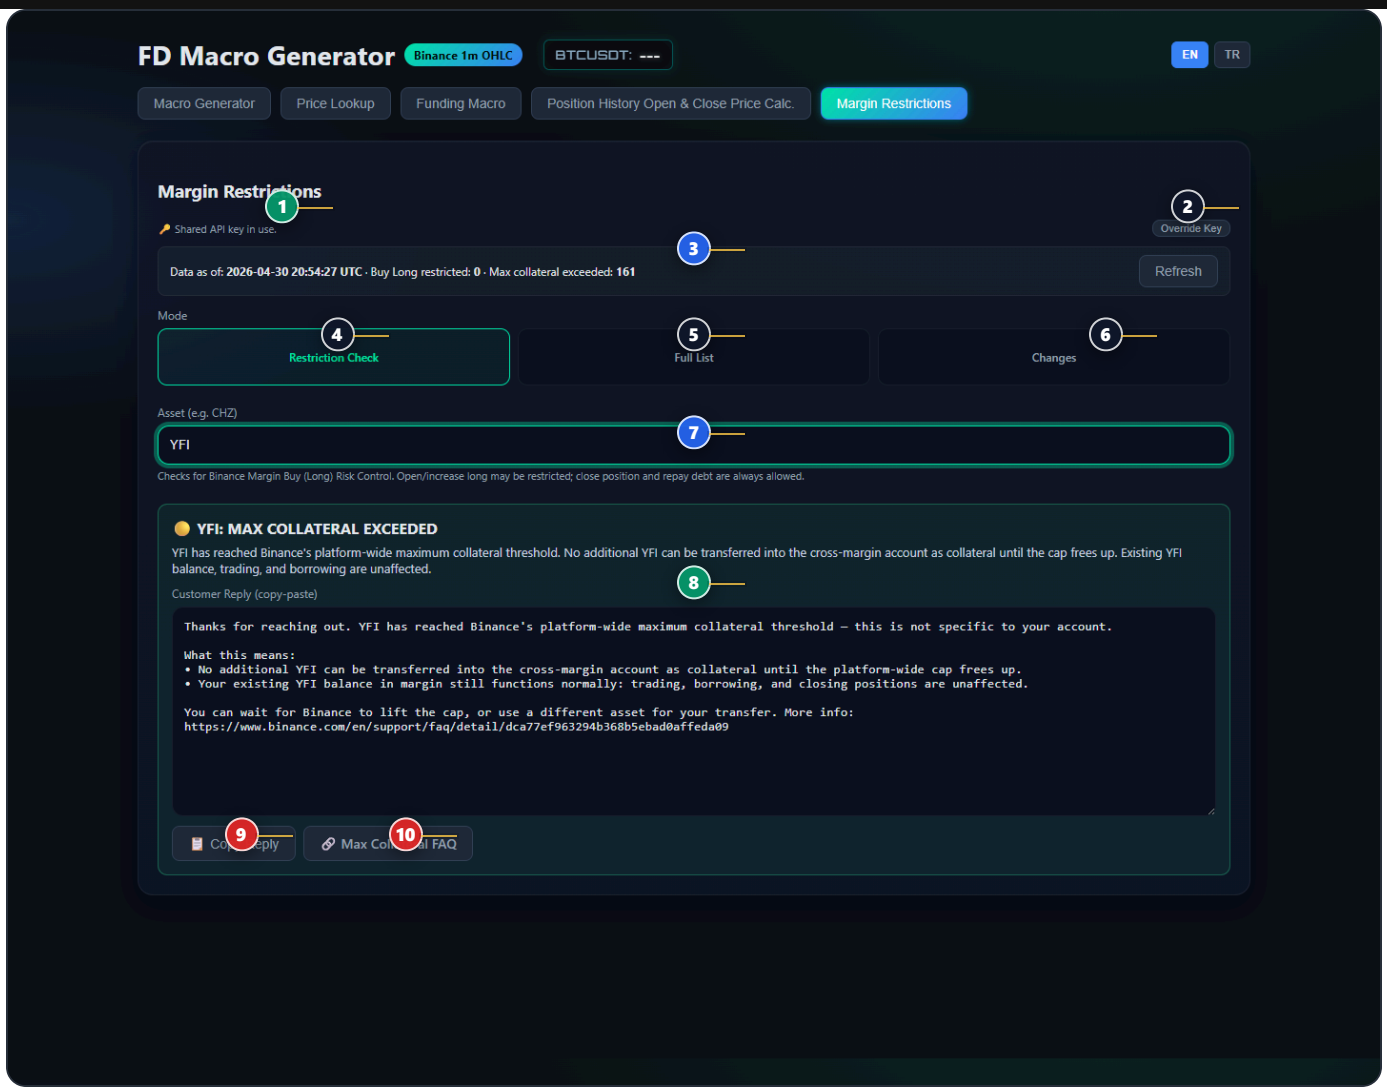
This tab checks Binance Margin restriction data from `GET /sapi/v1/margin/restricted-asset`. It is designed so agents do not need to provide an API key manually. The app uses the configured shared/default key path, and agents should simply refresh or search the asset.

Restriction meaning: `openLongRestrictedAsset` means Binance Margin Buy (Long) Risk Control is active. Users may be blocked from opening or increasing long positions, while close position and repay flows remain allowed. `maxCollateralExceededAsset` means the platform-wide collateral cap is reached, so additional transfers into cross margin as collateral can be blocked.

Agent workflow for Margin Restrictions

- Confirm the shared/default API key status is active, then use Refresh to pull the latest Binance list.
- Use Restriction Check for a single customer asset and copy the generated reply.
- Use Full List when the agent needs to scan or filter all restricted assets.
- Use Changes only to see whether restrictions were added or removed after refresh comparisons.

Restriction Check



1. Confirms the app can fetch restriction data without asking every agent for an API key.

2. Optional browser-local override. Do not use it in normal agent workflow unless instructed.

3. Shows fetch time and counts. Refresh requests the latest Binance restriction list.

4. Checks one asset and prepares a diagnosis plus customer reply.

5.

Shows all restricted assets in both categories.

6

Shows added or removed restrictions after refresh comparisons.

7

Enter a token symbol such as `YFI`, `CHZ`, or `ADA`.

8

Explains whether the asset is unrestricted, Buy Long restricted, max collateral exceeded, or both.

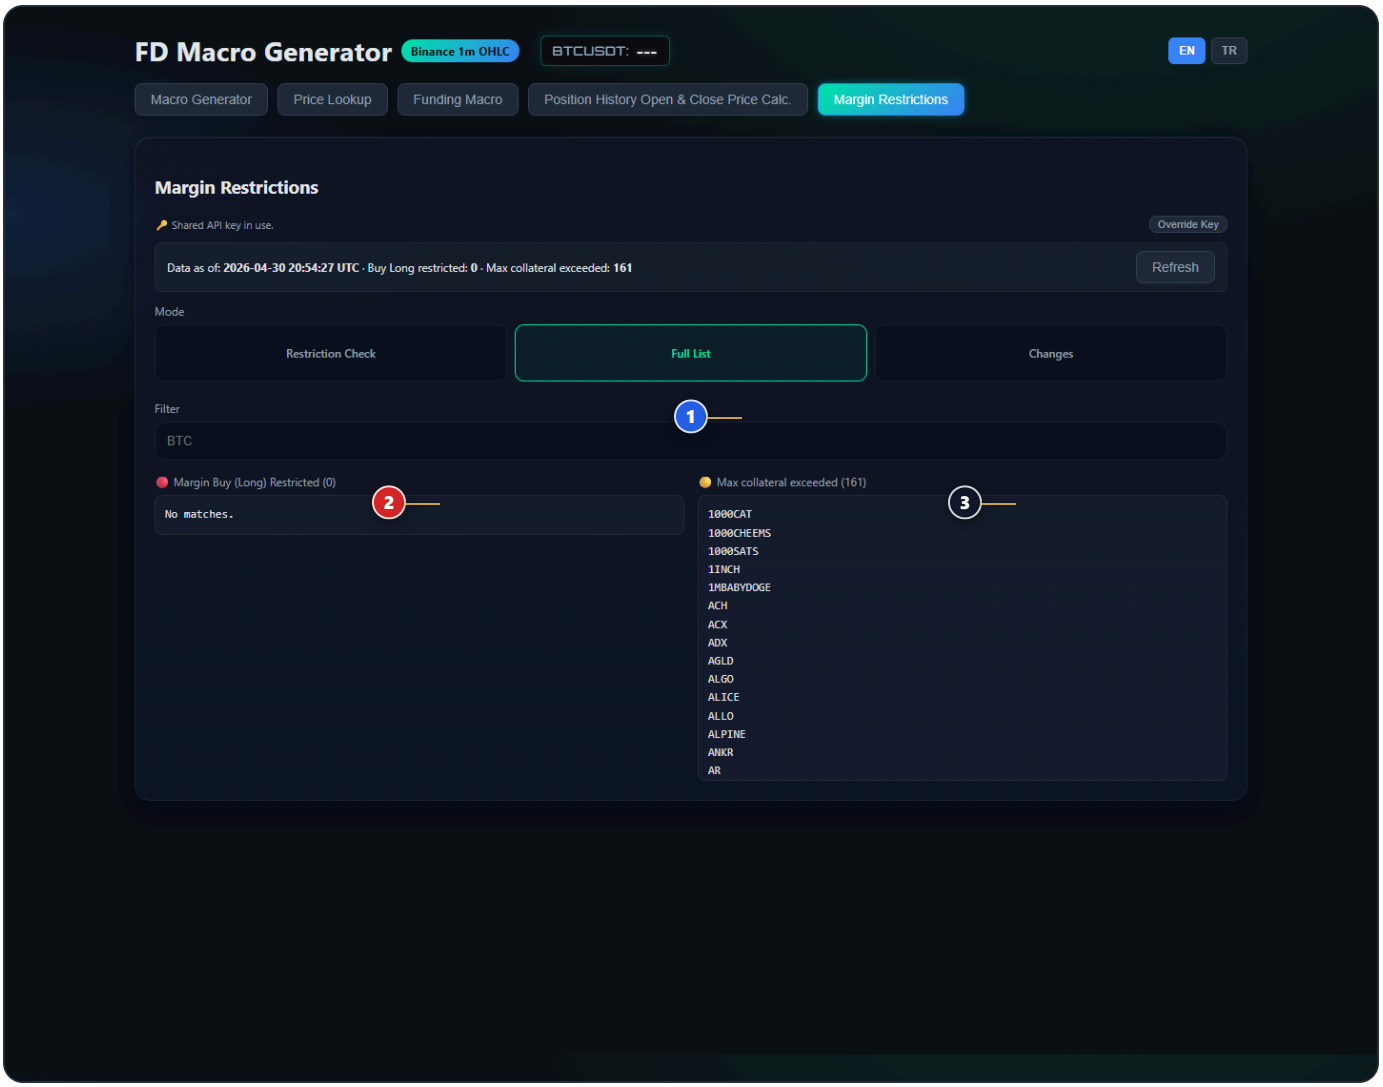
9

Copies the prepared customer response.

10

Opens the relevant Binance FAQ, such as Maximum Collateral Limit or Cross Margin Trading Risk Control.

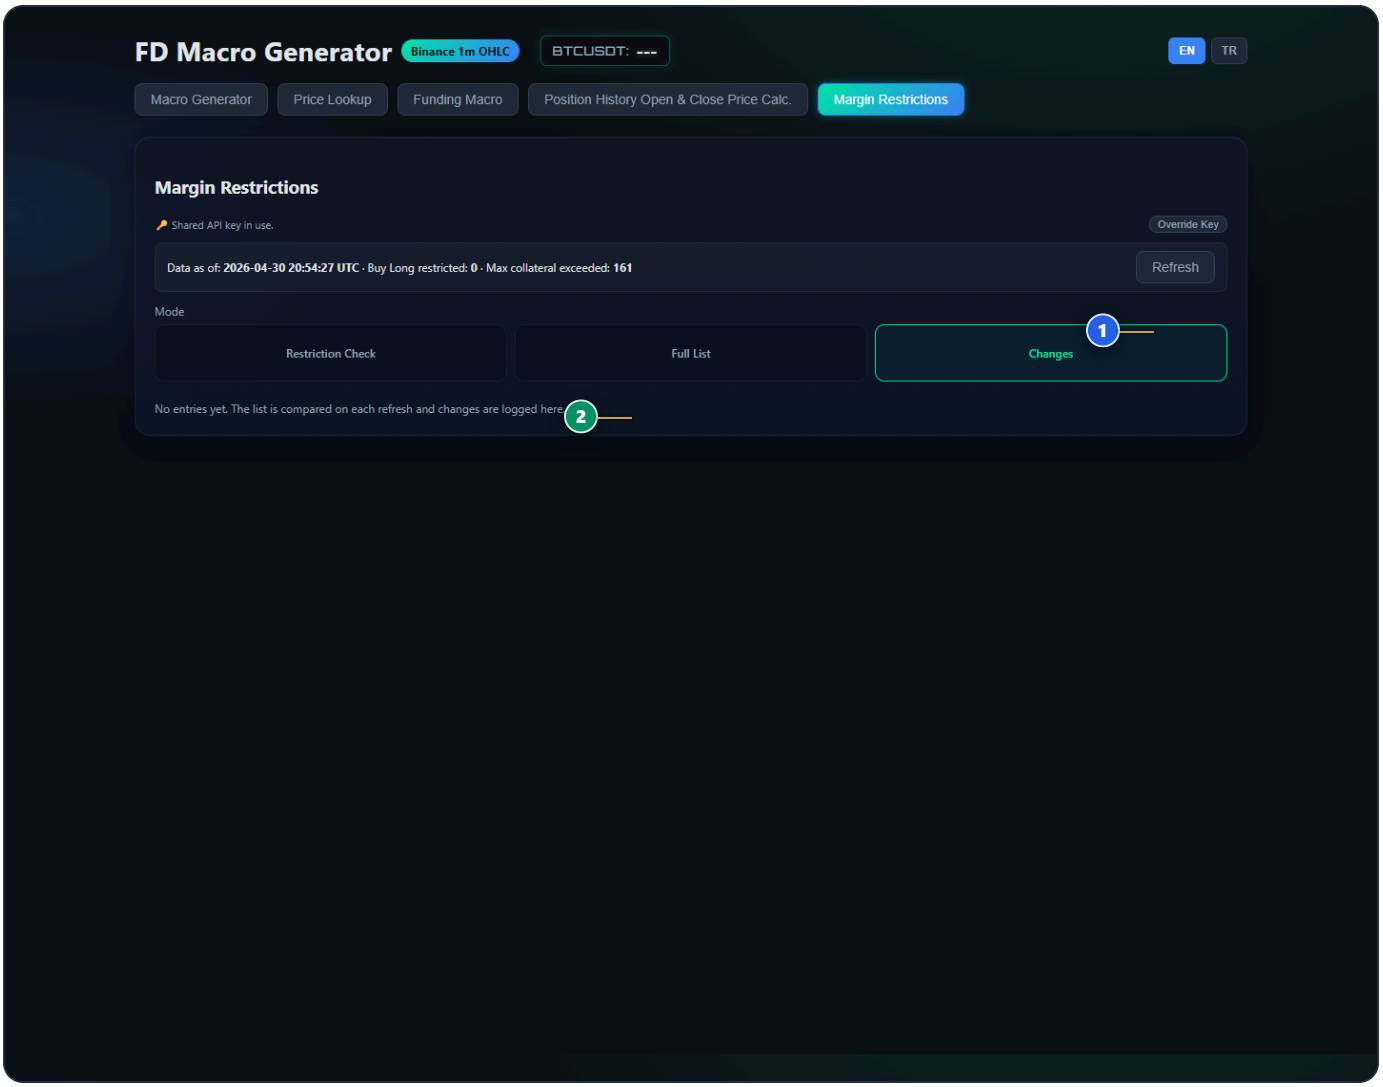
Full List and Changes



1. Filters both lists by token symbol.

2. Assets currently blocked from opening or increasing long positions.

3. Assets at Binance's platform-wide collateral cap.



1. Shows historical differences when a refresh adds or removes assets.

2. If no changes have been detected yet, the tab explains that entries are logged after refresh comparisons.

Example max collateral reply

```
YFI has reached Binance's platform-wide maximum collateral threshold. No additional YFI can be
transferred into cross margin as collateral until the cap frees up. Existing YFI balance, trading,
and borrowing are unaffected.
